RSA & Bijections: September 23

RSA Alice communicates to Bob. Eve wants to figure it out. The message is

$$m = D(E(m, s), s) \quad (1)$$

Bijections. A **bijective** function $f : S \rightarrow T$ is defined as

- One-to-one: $f(x) \neq f(x') \forall x, x' \neq x \in S$.
- Onto: $\forall y \in T \exists x \in S$ where $f(x) = y$.

Theorem: *Two sets have same size iff there is a bijection between them.* Relation to modular arithmetic:

- Can reverse mapping from S to T with inverse function $g : T \rightarrow S$ that maps outputs of f back to their input.
- Consider $f(x) = x + 1 \pmod m$. Is it 1-1?
- Well, consider $g(x) = x - 1 \pmod m$. It is the inverse of f , and so the function is one-to-one. **TIP:** To show a function is one-to-one, trying finding its inverse.
- **Theorem:** If $\gcd(a, m) = 1$, $ax \neq ax' \pmod m$ for $x \neq x' \in \{0, \dots, m-1\}$
- Consider output space $T = \{0a \pmod m, \dots, (m-1)a \pmod m\}$ and input $S = \{0, 1, \dots, (m-1)\}$. Want to show that $S = T$.
 - $T \subseteq S$, obvi.
 - one-to-one mapping from S to T , so $|T| \geq |S|$ and T is superset of S .
 - $\therefore S = T$.
- Result: Since $S = T$, inverse of $a \pmod m$ must exist because $1 \pmod m \in T$.

Example: RSA

- Public key: $(N = 77, e = 7)$ and $d = 43$ and $p \times q = 11 \times 7$.
- $E(2) = 2^e \bmod 77 = 51 \bmod 77 \longrightarrow D(51) = 51^{43} \bmod 77$
- 51^{43} is big. **Repeated squaring** to the rescue.
- $51^{43} = 51^{2^5 + 2^3 + 2^1 + 2^0} \bmod 77$. Calculate each factor alone $\bmod 77$ and use results from lower powers to calculate higher powers.
- How to actually do it¹: To compute $n^e \bmod p$, divide exponent e repeatedly by 2, flooring each time [Save sequence of numbers this produces]. Starting from smallest number (probably 1), successively take n raised to that power $\bmod p$. Use past results to help future ones. The last number in the sequence is e and you'll have $n^e \bmod p$.

Properties of e , d , and exponents in modular arithmetic.

- **Theorem:**

$$m^{ed} = m \bmod pq \text{ if } ed = 1 \bmod (p-1)(q-1) \quad (2)$$

- **Corollary:**

$$a^{k(p-1)+1} = a \bmod p \quad (3)$$

- **Lemma 1:** For any prime p and any a , b :² $a^{1+b(p-1)} \equiv a \bmod p$
- **Lemma 2:** \forall primes $p, q \neq p$ and $\forall x, k$: $x^{1+k(p-1)(q-1)} \equiv x \bmod pq$
- **Prime Number Theorem:** Let $\pi(N)$ denote the number of primes less than or equal to N . For all $N \geq 17$

$$\pi(N) \geq N / \ln N \quad (4)$$

¹See Discussion 5B

²Think Fermat's little theorem.

Important Notes on FLT³

- $\gcd(a, pq) = 1 \Leftrightarrow \gcd(a, p) = \gcd(a, q) = 1$
- Before expanding the exponent in $a^{(p-1)(q-1)}$, realize that it's the same as $(a^{p-1})^{q-1}$

Polynomials: September 28

Table of Contents Local

Scribe: Brandon McKinzie

Polynomials in modular arithmetic $P(x) \pmod p$ consist only of points in the domain $\{0, 1, \dots, p-1\}$.

Solve intersection of polynomials by equating and solving for x , use multiplicative inverses rather than dividing. "Whole world is $\pmod p$.

Theorem: There is exactly one polynomial of degree $\leq d$ ([optionally] with arithmetic modulo prime p) that **contains** $d+1$ (particular/given) points.

Secret: I'm going to give you $2+1$ points of a parabola, and the *secret* is that parabola's y-intercept.

Shamir's **k out of n scheme:**

1. Choose secret $s = a_0 \in \{0, \dots, p-1\}$ and randomly a_1, \dots, a_{k-1} .
 2. Let $P(x) = a_{k-1}x^{k-1} + \dots + a_0$.
 - 3 . The i th shared point is $(i, P(i) \pmod p)$.
- **Robustness:** Any k shares gives secret.
 - **Secrecy:** Knowing $\leq k-1$ points \Rightarrow any $P(0)$ is possible.

Solving polynomial given enough points \equiv **General linear system:**

- Given points: $(x_1, y_1), \dots, (x_k, y_k)$, Solve...

$$a_{k-1}x_1^{k-1} + \dots + a_0 \equiv y_1 \pmod p \quad (5)$$

$$\vdots \quad (6)$$

$$a_{k-1}x_k^{k-1} + \dots + a_0 \equiv y_k \pmod p \quad (7)$$

Interpolation

- **Goal:** Want to find $P(x) = a_2x^2 + a_1x + a_0 \pmod 5$ that contains $(1, 3), (2, 4), (3, 0)$.

1. Find $\Delta_1(x)$ defined such that, for all x above except $x = 1$, $\Delta_1(x) \equiv 0 \pmod{5}$ and evaluates to 1 at $x = 1$. Solution, as shown below, is to factor all $x - x_i$ together, evaluate at $x = 1$, and multiply the inverse of that to force/normalize $\Delta_1(x = 1) = 1 \pmod{5}$.

$$\Delta_1(x) = 3(x-2)(x-3) \pmod{5} \quad (8)$$

where 3 is inverse of $(1-3)(1-2) \pmod{5}$.

2. Repeat, constructing $\Delta_i(x) \forall x \in$ given points.
3. Now we have 3 polynomials that each evaluate to 1 only and 0 else for each given point. To make the *y-values* align and get desired polynomial, compute result:

$$P(x) = y_1\Delta_1(x) + 4\Delta_2(x) + 0\Delta_3(x) \pmod{5} \quad (9)$$

- General interpolation:

$$\Delta_i(x) = \frac{\prod_{j \neq i}(x - x_j)}{\prod_{j \neq i}(x_i - x_j)} \quad (10)$$

where, if in modular field, you don't technically "divide" the lower product; rather, you should read that as a multiplication by $\text{denom}^{-1} \bmod p$ (the multiplicative inverse).

- Construction via interpolation proves existence of unique solution.

Theorem: Any degree d polynomial has at most d roots.

Polynomial division

- Problem: Divide $4x^2 - 3x + 2$ by $(x - 3) \pmod{5}$.
- One approach is calculating while ignoring mod, then modding at end

$$\begin{array}{r} \quad \quad \quad 4x + 9 \\ x-3) \overline{4x^2 - 3x + 2} \\ \underline{-4x^2 + 12x} \\ \quad \quad \quad 9x + 2 \\ \quad \quad \underline{-9x + 27} \\ \quad \quad \quad 29 \end{array}$$

and answer is then $29 \bmod 5 = 4$. You can also just mod 5 everything as you go, too.

- In general, dividing $P(x)$ by $(x - a)$ gives $Q(x)$ and remainder r . i.e.

$$P(x) = (x - a) Q(x) + r \quad (11)$$

Lemma 1: $P(x)$ has root a iff $P(x)/(x - a)$ has remainder 0.⁴

Lemma 2: $P(x)$ has d roots; r_1, \dots, r_d then⁵

$$P(x) = c(x - r_1)(x - r_2) \cdots (x - r_d) \quad (12)$$

Polynomials Discussion

1. **How many polynomials?** (I'll express my degree of certainty for each of my answers as a footnote)

- (a) Strictly speaking, $P(2)$ can only have 5 values since $GF(5)$. The number of distinct polynomials is $5 \times 5 \times 5 = 125$.⁶
- (b) The number of different pairs are $5^2 = 25$. The number of polynomials here is the number of distinct pairs of $P(i \neq 0), P(j \neq 0, i)$. This is $(5 \times 4) \times (5 \times 3) = 300$.⁷
- (c) If we know k values, then we need $(d + 1) - k = (d - k) + 1$ more points to uniquely determine any polynomial. The next point can have $p - k$ possible values for x , and each of those can have p possible y values, for a total of $(p - k) \times p$ unique choices for the next point alone. For subsequent choices, the number of possibilities decreases by a factor of p . Therefore, the number of different polynomials we could obtain, given that we are in $GF(p)$, is⁸

Error: The main error in your line of thought is that many of those polynomials would be the same one. Although polynomials are indeed definable by a set of points, many such sets can define a single polynomial. If you're going to take this approach, you need to say more like: We have $(d-k)+1$ points, each of which could take on p different values, so the number of *distinct* polynomials is $p^{(d-k)+1}$. Ta-da.

2. **Lagrange Interpolation.** I have an issue with their wording: Should just say "of degree 3" since it says unique. Whatever⁹

- (a) $\Delta_{-1}(x) = \frac{(x-0)(x-1)(x-2)}{(-1-0)(-1-1)(-1-2)}$
- (b) $\Delta_0(x) = \frac{(x+1)(x-1)(x-2)}{(1)(-1)(-2)}$
- (c) $\Delta_1(x) = \frac{(x+1)(x-0)(x-2)}{(2)(1)(-1)}$
- (d) $\Delta_2(x) = \frac{(x+1)(x-0)(x-1)}{(3)(2)(1)}$

⁴To prove: use 11

⁵To prove: induction on number of roots. Take advantage of Lemma 1.

⁶Certainty: 95 percent.

⁷Certainty: 90 percent

⁸Certainty: ~~95 percent~~ ~~More like 40 percent~~ 0 Percent because I know I was wrong now.

⁹Certainty: 90 percent only because algebra errors.

$$(e) \ p(x) = 3\Delta_{-1}(x) + 1\Delta_0(x) + 2\Delta_1(x) + 0\Delta_2(x)$$

3. **Secret sharing** Generate a degree 2 polynomial. Give each TA two points of it. Give each reader 1 point of it.¹⁰

Polynomials Note

- **General Definitions**

- **Polynomial division:** If we have a polynomial $p(x)$ of degree d , we can divide by a polynomial $q(x)$ of degree le by using long division. The result will be: $p(x) = q(x)q'(x) + r(x)$ where¹¹ $\deg(r) < \deg(p)$. Subtlety: When you rewrite p in quotient/remainder form like this, where you've explicitly said what you're dividing by (q), then $\deg(r) < \deg(q)$ by definition.

- **Property 1:** A non-zero polynomial of degree d has at most d roots.

- **Claim 1** $[p(a) = 0] \Rightarrow [p(x) = (x - a)q(x)]$ where $\deg(p) = d$ and $\deg(q) = d - 1$.
- **Claim 2:**¹² If $p(x)$ has d distinct roots a_i , then $p(x)$ can be written as $p(x) = c(x - a_1)(x - a_2) \cdots (x - a_d)$.

- **Property 2:** Given $d + 1$ pairs with all x_i distinct \exists unique $p(x)$ of degree (at most) d such that $p(x_i) = y_i \forall i \in \{1, \dots, d + 1\}$.

- **Counting**

- Can specify any $d + 1$ polynomial with either (a) it's coefficients (coefficient representation) a_i , or (2) a set of $d + 1$ points (value representation) contained by the polynomial. Can convert rep (a) to rep (b) by evaluating at the points. Can convert (b) to (a) with lagrange interpolation.
- IMPORTANT: When they say "how many distinct polynomials go through these.." and whatever, they apparently always assume that the x points are ordered, and you're only interested in the value of $p(x)$ at the next, as of yet unspecified, x point. Wtf?

- **Exhaustive List of PROOF TECHNIQUES:**

- Rewriting $p(x)$ in quotient + remainder form and exploiting properties of roots, degree of the quotient, etc.
- Induction on the degree d of a polynomial.

¹⁰Certainty: 70 percent. Question seems open-ended and the wording is shit

¹¹Check Piazza for followup on my question regarding this

¹²Claim 2 \implies Property 1

- When thinking about number of polynomials in $[\dots]$, remember that a polynomial can be uniquely defined by its *coefficients*. Equivalently, can think of as defined by $d + 1$ points; Note that there can be *many* such sets of $d + 1$ points that define the same polynomial.

Discrete Math and Probability

Fall 2016

Erasure Coding: September 30

Table of Contents Local

Scribe: Brandon McKinzie

- Lecture outline:
 - Finish polynomials and secret sharing
 - Finite fields: Abstract Algebra
 - Erasure Coding
- Note: the $d + 1$ points needed to specify any polynomial must have different x values (obvi).
- **Finite Fields**
 - Proofs of uniqueness haven't depended on whether x is reals, rationals, complex numbers. . . but not integers since no multiplicative inverses. Only works if modulo a prime p and finite element sets.
 - Can still generalize all to **finite fields**. Denote arithmetic mod p as field F_p or $GF(p)$.
 - Field def (informal): set with operations corresponding to addition/mult/div.
 - **Fact:** The number of degree d polynomials over $GF(m)$ is m^{d+1} .
- Revisit **efficiency** of polynomial secret sharing (k of n).
 - Need $p > n$ to hand out n shares.
 - For b -bit secret, need¹³ $p > 2^b$.
 - **Theorem:** There is always a prime between n and $2n$.
- **Erasure Codes** (error correcting codes)
 - **Problem:** Want to send message with n packets. Lossy channel: loses k packets.
 - **Question:** Can you send $n + k$ packets and recover message?¹⁴
 - Solution Idea: Use polynomials. “Any n packets (out of the $n + k$) should allow reconstruction of original n packet message.”¹⁵

¹³so you can share any secret you want. Good to choose $p = 2^b + 1$.

¹⁴ $n + k$ because, since we know k packets out of the n will be lost, we should send $n + k$ packets if we want a total of n packets to be received.

¹⁵Think polynomial secret sharing.

- Restated: Any n **point values** allow reconstruction of degree $n - 1$ polynomial.
- **Erasure coding scheme:** Message consists of n packets denoted m_0, m_1, \dots, m_{n-1} . Each m_i is packet.
 1. Choose prime $p > 2^b$ for packet size b (num bits).
 2. $P(x) = m_{n-1}x^{n-1} + \dots + m_0 \pmod{p}$.
 3. Send $P(1), P(2), \dots, P(n+k)$.
- Any n of the $n+k$ gives polynomial, and thus the message.
- Comparison: Erasure codes vs. secret sharing.
 - Secret sharing: each share is size of whole secret.
 - Erasure: each share (a packet) is size $1/n$ of whole secret.
- **Example:** Erasure codes
 - Send message 1, 4, 4 containing $n = 3$ numbers, up to $k = 3$ of which can be lost.
 - Make $P(1) = 1$, $P(2) = 4$, and $P(3) = 4$.
 - Work modulo 7 to accommodate at least $n+k = 6$ packets.
 - Can construct via linear system:¹⁶

$$P(1) = a_2 + a_1 + a_0 \equiv 1 \pmod{7} \quad (13)$$

$$P(2) = 4a_2 + 2a_1 + a_0 \equiv 4 \pmod{7} \quad (14)$$

$$P(3) = 2a_2 + 3a_1 + a_0 \equiv 4 \pmod{7} \quad (15)$$

$$(16)$$

so $P(x) = 2x^2 + 4x + 2$. Send packets $(1, 1), (2, 4), (3, 4), (4, P(4)), (5, P(5)), (6, P(6))$.

Don't forget to take mods

Error Correcting Codes

- **Erasure Errors:** (missing packets)
 - Note: I'm only writing info here that I didn't write in the previous section.
 - If each packet is a b -bit string, choose prime p to be any prime larger than 2^b .
 - Be careful to ensure that $n+k \leq p$, which is usually pretty easy.
 - If receiver only gets $n-1$ of the packets, there are exactly p polynomials of degree at most $n-1$ that agree with the received packets.

¹⁶Form is always the same: Plug in values for x into $a_{k-1}x^{k-1} + \dots + a_1x + a_0 \pmod{p}$. Don't forget to take mod on all coefficients!

- “This error-correcting scheme is therefore **optimal**: it can recover the n characters of the transmitted message from any n received characters, but recovery from any fewer characters is impossible.”
- To prove that the linear system always has a solution and that it is unique (which is true), hint is to show that a certain determinant is non-zero.
- **General Errors** (individual packets may be corrupted, but all are transmitted)
 - **DISTINCTION BETWEEN ERASURE**: Rather than the message being the coefficients of the polynomial, now want to encode as what polynomial evaluates to. fml.
 - One can still guard against k general errors by transmitting only $2k$ additional packets or characters¹⁷.
 - Encoded message: $c_1, c_2, \dots, c_{n+2k}$ where $c_j = P(j)$ for $1 \leq j \leq n + 2k$. At least $n + k$ of these are received uncorrupted¹⁸
 - Receiver has to find $P(x)$. Know that $P(i) = r_i$ on at least $n + k$ points, where r_i denotes the i th *received* value. There are k points where $P(i) \neq r_i$ because they have been corrupted (changed) during the transmission process.
 - If e_1, \dots, e_k packets corrupted, define degree k polynomial $E(x)$ as follows, and with relationship to $P(x)$:

$$E(x) = (x - e_1)(x - e_2) \cdots (x - e_k) \quad (17)$$

$$P(i) E(i) = r_i E(i) \quad (18)$$

for $1 \leq i \leq n + k$ where received points are of form (i, r_i) . For any $i = e_i$, $E(i) = 0$. This is true because: (1) out of the $n + 2k$ received, $n + k$ match the desired $P(x)$ correctly, i.e. $P(i) = r_i$ for $n + k$ points and eq 18 is obviously true. For the other points (the ones that got corrupted), $P(i)$ will be some (as of yet unknown) value that is not r_i . However, eq 18 is still true because $E(x) = 0$ for any x that was corrupted.

- Eq 18 is really $n + 2k$ linear equations with $n + 2k$ unknowns.

* Unknowns are the coefficients of $E(x)$ and $Q(x) := P(x)E(x)$.

$$Q(x) = a_{n+k-1}x^{n+k-1} + \cdots + a_1x + a_0 \quad (19)$$

$$E(x) = (1)x^k + b_{k-1}x^{k-1} + \cdots + b_1x + b_0 \quad (20)$$

- Convention seems to be that, if we want to send a message of size n , we encode that message directly **in order** as $P(1), \dots, P(n)$, starting for some reason at 1. We then encode the extra k parts as ordered eval of $P(n + 1), \dots, P(n + k)$.

¹⁷only twice as many as in the erasure case

¹⁸Goal is still for receiver to determine the unique polynomial $P(j)$.

- The **degree of $P(x)$** is $\deg(P) = n - 1$. In other words, we map the desired n -point message to $(n - 1) + 1$ points defining the degree $n - 1$ polynomial.
- **Exhaustive procedure/example:**
 - * Setup: Working over $GF(7)$. Message has $n = 3$ characters.
 - * **UNKNOWN TO RECEIVER:** Desired message: 3, 0, 6. Then we need $P(x)$ uniquely defined by the points $(1, 3), (2, 0), (3, 6)$. Therefore, $P(x)$ is degree $n - 1 = 2$ with $P(x) = x^2 + x + 1 \pmod{7}$.
 - * **KNOWN TO RECEIVER:** Know that $n = 3$, $k = 1$, and therefore they know that the received message of size $n + 2k = 5$ has 1 corrupted letter. They know that the following polynomials take the respective forms¹⁹

$$E(x) = x + e_0 \tag{21}$$

$$Q(x) = q_3x^3 + q_2x^2 + q_1x + q_0 \tag{22}$$

$$= r_x E(x) \tag{23}$$

- * Don't forget to take mods of coefficients along the way.
- * **Q:** Given that we know $k = 1$ points will be corrupted, why is it *exactly* that we need to send $n + 2k = 5$ points? **A:** See below. Basically, it is so we can guarantee that the recovered polynomial P is unique (and the one we sent).

¹⁹Fact: For any polynomials P and Q , it is true that $\deg(PQ) = \deg(P) + \deg(Q)$.

General Errors: October 3

Table of Contents Local

Scribe: Brandon McKinzie

- Only going to write new information here.
- **Problem:** Communicate n packets $m_1 \dots m_n$ on noisy channel that corrupts $\leq k$ packets. Notice that it is $\leq k$ now.
- **Reed Solomon Code:** Make $P(x)$ of degree $n - 1$.

$$P(1) = m_1; \dots; P(n) = m_n \quad (24)$$

- Send $P(1), \dots, P(n + 2k)$.
- **Why $n + 2k$?**
- ²⁰. Okay I think I know why we need $n + 2k$ points. It is related to the fact that we need to guarantee the receiver will reconstruct the *unique* polynomial $P(x)$ as opposed to some other polynomial.
- Claim: If two polynomials $P(x)$ and $P'(x)$ satisfy $P(i) = r_i$ and $P'(i') = r'_i$ for their own (separate) sets of $\geq n + k$ points in the received message of size $n + 2k$, then $P(x) = P'(x)$.
- Proof: We know that $\leq k$ (so at most k) packets are corrupted. This means that $P(x)$ and $P'(x)$ share *at least* n points in common (out of their respective $n + k$ point sets), i.e. where for any of these points r_j , it is true that $P(j) = r_j = P'(r_j)$. Since they are degree $n - 1$ polynomials that are uniquely defined by n points, it must be that $P(x) = P'(x)$.
- Lec then goes over example of 3, 0, 6 from the note and works through it.
- jargon: calls $E(x)$ the **error locator polynomial**.
- kind of annoyed that he keeps saying things like $P(x)$ is degree $\leq n - 1$, when the note seems to just say "equals". Come back later and explain whether or not I should care.
- However, says $\deg(E) = k$.

Error Review & Infinity: October 5

Table of Contents Local

Scribe: Brandon McKinzie

- Continues on general-error encoding example from note.
- Technique is called **Berlekamp-Welch**.²¹
- Wants to answer existence and uniqueness of $P(x)$ and $Q(x)$. Existence is easy. $n+2k$ in $n+2k$ unknowns can be solved so yes it exists.
- uniqueness requires proof by contradiction assuming two different solutions exist. I don't see how this is any different from my claim/proof in the previous lecture. Time: 17:00. Identical proof as in note though regarding $EQ = Q'E$.
- **Infinity an Uncountability**. Proof techniques are enumeration and constructing bijections.
- **Countably infinite**: A set is countably infinite if its elements can be put in one-to-one correspondence with the set of natural numbers.
- Determining if two sets are **same size**.
 - Make function $f : A \rightarrow B$.
 - Show f is one-to-one, defined as $\forall x, y \in A, x \neq y \implies f(x) \neq f(y)$. Show f is onto, i.e. $\forall s \in B, \exists c \in A, s = f(c)$.
 - **Isomorphism principle**: If there exists bijection $f : A \rightarrow B$, then $|A| = |B|$ (the cardinality of A is the same as cardinality of B).
- **Number of subsets of $S = \{a_1, \dots, a_n\}$** .
 - Equal to number of binary n -bit strings. In other words, there exists a bijection $f : \text{subsets} \rightarrow n\text{-bit strings}$.
 - **Proof**: For some subset x of $\{a_1, \dots, a_n\}$, define

$$f(x) = \left(g(x, a_1), \dots, g(x, a_n) \right) \quad (25)$$

$$g(x, a) = \begin{cases} 1 & a \in x \\ 0 & \text{otherwise} \end{cases} \quad (26)$$

²¹This technique, i guess, *uses* reed-solomon code. Whatever.

- Example: $S = \{1, 2, 3, 4, 5\}, x = \{1, 3, 4\}$. Then $f(x) = (1, 0, 1, 1, 0)$.
- The cardinality of the **Power set** of S is

$$|\mathcal{P}(S)| = |\{0, 1\}^n| = 2^n \quad (27)$$

which is the number of n -bit binary strings, and *therefore* the number of subsets is also 2^n since f is a bijection.

- **Infinity** [38:00]

- Natural numbers = “the counting numbers”.
- Any set S is **countable** if there exists a bijection between S and *some subset of* \mathbb{N} .
- If the subset of \mathbb{N} is finite, then S has **finite cardinality**. If infinite subset then countably infinite and say it has “the same cardinality as \mathbb{N} ”.
- Note, if a bijection exists from A to B , then we automatically know one exists from B to A because function inverse guaranteed.
- Comparing cardinality of \mathbb{Z} to that of \mathbb{N} : Define $f : \mathbb{N} \rightarrow \mathbb{Z}$ where

$$f(n) = \begin{cases} n/2 & \text{if } n \text{ even} \\ -(n+1)/2 & \text{odd} \end{cases} \quad (28)$$

and check (1) one-to-one by proof by cases on $x, y \in \mathbb{N}$ and combinations of one/both being even/odd, and (2) onto by for $z \in \mathbb{Z}$, cases where its negative/nonnegative and showing that its pre-image would be $\in \mathbb{N}$.

Scribe: Brandon McKinzie

- **Lists** have natural ordering property where position of item in list is a natural number. One way of showing if list is countable is by **enumeration** of elements in that set. Enumerability \equiv countability.
- When enumerating, need to be careful that each element has a *finite* specified position in the list.
- **Lemma:** Any subset T of a countable set S is countable.
- All countably infinite sets have the same cardinality.
- For finite sets S_1 and S_2 , cardinality of $S_1 \times S_2$ is $|S_1| \times |S_2|$.²²
- **Cantor's diagonalization** for analyzing the cardinality of \mathbb{R} .
 - Try enumerating. View as a table. Construct a number along the diagonal: digit i is 7 if row i 's i th digit is not 7, 6 otherwise. Implies that the diagonal number is not in the list²³, but it is somehow in \mathbb{R} , which is a **contradiction**.
 - Note: We can say that, *since* the numbers in the range $[0, 1]$ are uncountable, and since they are a subset of \mathbb{R} , that \mathbb{R} is uncountable.
- Can show a bijection between two uncountable sets, e.g. $f : \mathbb{R}^+ \rightarrow [0, 1]$.

Computability:

- **Barber Paradox.** Why is this supposed to be interesting? Proof by cases leads to contradiction.
- Any definable collection is a set. Example:

$$\exists Y \forall x (x \in Y \iff P(x)) \quad (29)$$

and “ y is the set of elements that satisfies $P(x)$.” Can apply to barber paradox.

- Key notion here is **self-reference**.

²²Note: seems to suggest that $\mathbb{N} \times \mathbb{N}$ is undefined. But countable... Check.

²³If it were, say, the j th element of the list, then by definition its j th element could not be its j th element. Don't hurt yourself, it's simple.

- The **halting problem**: write program that checks if other program halts: $HALT(P, I)$ where P is a program, I is input. Determines if $P(I)$ [P run on I] halts or loops forever. Program itself is some text string, which is why it (a program) can be fed as input to a program. *This enables self-reference in computation. One program executing on itself is possible.*
- HALT does **not** exist. Proof: Assume there is a program called HALT and a program TURING(P).
 1. If $HALT(P, P) = \text{"halts"}$. then define Turing such that it goes into an infinite loop.
 2. Otherwise, Turing halts immediately. It basically does the opposite.
 3. Assumptions: there is a program HALT and text that are both the programs TURING and HALT.
 4. Question: Does Turing(Turing) halt? Proof by cases.
 - Assume it does halt. Then $HALT(\text{Turing}, \text{Turing}) = \text{halts}$. Then we TURING(turing) loops forever. Contradiction.
 - Assume it loops forever. Then $HALT(\text{turing}, \text{turing}) \neq \text{halts}$. Then Turing(turing) halts. Contradiction.

and so program HALT does not exist.

Counting: October 10

Table of Contents Local

*Scribe: Brandon McKinzie***Computability Wrap-up:**

- Goes over Turing machine. Infinite tape with characters. Can be in a state, read a character. Move left/right and read/write character.
- Universal turing machine: tape could be a description of a ... turing machine.
- Church proved equivalent theorem about **Lambda calculus**.
- Godel proved his **incompleteness theorem**: any formal system is either inconsistent [false statement can be proven] or incomplete [there is no proof for some sentence in the system]. Godel also showed every statement corresponds to a natural number. wtf.

Counting:

- Related to questions of the form “How many ... given [condition]?”
- **Product Rule**: Objects made by choosing from n_1 then n_2 , ..., then n_k , then the number of objects is

$$n_1 \times n_2 \times \cdots \times n_k \quad (30)$$

- **Permutations**: General case is “how many different samples of size k from n numbers **without replacement**.” Answer:

$$n \times (n-1) \times \cdots \times (n-k+1) = \frac{n!}{(n-k)!} \quad [{}^nP_k] \quad (31)$$

- If order doesn't matter, count ordered objects and then divide by number of orderings²⁴. Have n objects and want to choose k ?

$$\frac{n!}{(n-k)! \times k!} = \binom{n}{k} \quad (32)$$

²⁴Calls this “second rule of counting.” The first rule is the produce rule.

- Suppose sampling with replacement but order doesn't matter. Famous example is **Stars and bars**: *How many ways can Bob and Alice split 5 dollar bills?* For each of 5 dollars pick Bob or Alice (2^5), “then divide out order??” Let a denote number of dollars for Alice, similarly for Bob such that $a + b = 5$, or in more general case $a + b = k$. There are apparently $k + 1$ ways.
- General case[48:00]: If want to split up between, say, $k = 3$, can split with **stars and bars**: $**|*|**$. Each sequence of stars and bars \implies split.
- **Counting rule**: If there is a 1-to-1 mapping between two sets, they have the same size.
- **Sum rule**: For disjoint S and T , $|S \cup T| = |S| + |T|$.
- **Inclusion/Exclusion**: $\forall S, T, |S \cup T| = |S| + |T| - |S \cap T|$.

General stars and bars: k stars $n - 1$ bars. There are

$$\binom{n+k-1}{n-1} = \binom{(n-1)+k}{n-1} = \binom{n+k-1}{k} \quad (33)$$

... in other words, $n + k - 1$ positions from which to choose $n - 1$ bar positions. WIKIPEDIA VERSION:

Theorem one

$\forall n, k \in \mathbb{Z}^+$: the number of k -tuples of **positive** integers, whose sum = n , is $\binom{n-1}{k-1}$
 Translation: If each person must get something, there are $\binom{n-1}{k-1}$ ways to split n stars up among $k + 1$ people.

Theorem two

$\forall n, k \in \mathbb{Z}^+$: the number of k -tuples of **non-negative** integers, whose sum = n , is $\binom{n+k-1}{k-1} = \binom{n+k-1}{n}$. Translation: In general case, there are $\binom{n+k-1}{k-1} = \binom{n+k-1}{n}$ ways to split n stars up among $k + 1$ people.

Since the above is confusing, here is the clearest possible way I can state it: If asked, how many ways to split up n [things] among k [people]? The answer is always

$$\binom{n+k-1}{k-1} \quad (34)$$

Examples

- How many 3-bit strings?

- How many outcomes for k coin tosses? 2^k .
- How many 10 digit numbers? 10^k .
- How many n digit base m numbers? m^n .
- How many **functions** f mapping S to T ? $|T|^{|S|}$, because $\forall s_i \in S$ have $|T|$ choices for $f(s_i)$.
- How many **polynomials** of degree d modulo p ? p^{d+1} coefficient choices and/or choices of the unique $d + 1$ points (both lead to same answer).
- How many 10 digit numbers *without repeating a digit*? $10 \times 9 \times \dots \times 1 = 10!$.
- How many 1-to-1 functions from $|S|$ to $|S|$? $|S|!$.
- How many poker hands? Number of orderings for a given poker hand is $5!$, so answer is $52!/(5!47!)$.
- How many different 5 star and 2 bar diagrams? 7 positions in which to place the 2 bars. $\binom{7}{2}$ ways splitting 5 dollars among 3 people.

Combinatorial Proofs

Let $|A| = n$. **Prove** $\binom{n}{k+1} = \binom{n-1}{k} + \binom{n-2}{k} + \cdots + \binom{k}{k}$.

- LHS. Number of subsets of size $k + 1$ from set of size n .
- RHS. Ask yourself: What's another way I could find all subsets of size $k + 1$?
 - Well, I could count the number of subsets that include the element $\min(A)$. This means I have k elements out of the remaining $n - 1$ to choose from, i.e. $\binom{n-1}{k}$. That takes care of all subsets including $\min(A)$.
 - What about subsets where the smallest element is the *second-smallest* element in A ?²⁵ Now we have k elements out of the remaining $n - 2$ to choose from, i.e. $\binom{n-2}{k}$, and the pattern emerges.
- Therefore, the j th term on the RHS represents the number of subsets of size k where the smallest item in the (j th) subset is the j th smallest element in A .

Textbook (Rosen) Notes

- If A_1, \dots, A_m are finite sets, then number of elements in the Cartesian product of these sets is

Equation

$$|A_1 \times \cdots \times A_m| = |A_1| \cdots |A_m| \quad (35)$$

- An **r-combination** of elements of a set is an unordered selection of r elements from the set. Thus, an r -combination is simply a subset of the set with r elements. The number of r -combinations from a set of n elements is often denoted as $\binom{n}{r}$.

²⁵Notice that all such subsets do not include *any* of the subsets counted in the previous bullet point.

Binomial theorem and related stuff.

Binomial Theorem

$$(x + y)^n = \sum_{j=0}^n \binom{n}{j} x^{n-j} y^j \quad (36)$$

which can be proved by counting the number of $x^{n-j}y^j$ terms. Since we have n products of sums $x + y$, we would need to *choose* $n - j$ x 's from the n sums. But this is just $\binom{n}{n-j} = \binom{n}{j}$. Damn.

Corollaries to the Binomial Theorem

$$\sum_{k=0}^n \binom{n}{k} = 2^n \quad (37)$$

$$\sum_{k=0}^n (-1)^k \binom{n}{k} = 0 \quad (38)$$

$$\sum_{k=0}^n (2)^k \binom{n}{k} = 3^n \quad (39)$$

where all of these can be proven very easily using the Binomial Theorem (Hint: Think about what each implies about the values of x and y).

Other useful Identities.

Pascal's Identity and Vandermonde's Identity

$$\binom{n+1}{k} = \binom{n}{k-1} + \binom{n}{k} \quad \text{PASCAL} \quad (40)$$

$$\binom{m+n}{r} = \sum_{k=0}^r \binom{m}{r-k} \binom{n}{k} \quad \text{VAND.} \quad (41)$$

Note: It seems pretty popular to think about $\binom{n}{k}$ as “the number of bit strings of length n containing k ones.”

Midterm 2 Review: October 22

Table of Contents Local

Scribe: Brandon McKinzie

Bijections/Sets

- **[FA15.4.a]** If need bijection $f : (1, \infty) \rightarrow (0, 1)$, don't get too caught up with how any particular number should be mapped. Instead, think about what functions *over the given domain* map a positive real number above 1 to the interval 0, 1. The function they use is $1/x$. Then show it's one-to-one and onto in order to prove bijection.
- To check if two sets A, B are *equal* (not just same size), check both that $A \subseteq B$ and $B \subseteq A$.

RSA/Modular Arithmetic

- **Q [FA15.1.d]**: Given just N and e , how to quickly find d ? **A**: You can't unless you know the factors of N .
- **Q [FA15.1.e]**: What is the general meaning of 'signature of x'?
- Write everything here about meaning of *relatively prime to [a number]* and what it implies/how to think about it.
 - ★ Definition: a rel prime to b iff $\gcd(a, b) = 1$
 - ★ Means that the two numbers share no common factor.
 - ★ Multiplicative inverse of a exists mod b and vice versa.²⁶
 - ★ If inverse exists, then it is *also* relatively prime with the other number. This should be obvious because the inverse of the inverse exists (it is the original number) which means it must be rel prime.
 - ★ **GENERAL FLT**: For any modulus n and any integer a coprime to n ,

$$a^{\varphi(n)} \equiv 1 \pmod{n} \quad (42)$$

where $\varphi(n)$ denotes **Euler's totient function** which counts the number of integers

²⁶Does it matter if one number is bigger than the other? **A: No it does not matter.**

between 1 and n that are coprime with n .

$$\varphi(n) = n \prod_{p|n} \left(1 - \frac{1}{p}\right) \quad (43)$$

$$\gcd(m, n) = 1 \implies \varphi(mn) = \varphi(m)\varphi(n) \quad (44)$$

$$\varphi(p^k) = p^k \left(1 - \frac{1}{p}\right) \quad (45)$$

- **Chinese Remainder Theorem**: a theorem of number theory, which states that, if one knows the remainders of the division of an integer n by several integers, then one can determine uniquely the remainder of the division of n by the product of these integers, under the condition that the divisors are pairwise coprime.
- Any RSA scheme is considered broken/breakable if knowing N allows one to deduce the value of $(p-1)(q-1)$, where you're only given N , not its factors. This is because, equivalently, breaking RSA means figuring out the value of $d = e^{-1} \pmod{(p-1)(q-1)}$.
 - Also, unbreakable means at least as difficult as ordinary RSA. So, if you can make a bridge between the problem you're doing and the problem of ordinary RSA (given just N, e , find d), that suffices.
 - **Q**: How to prove correctness of RSA?

Polynomials/Modular Arithmetic

→ Walkthrough of how smart person would approach “What is $3^{240} \pmod{77}$ ”

1. Oh, 77 is 11×7 , so I could think of as $\pmod{77} = \pmod{pq}$.
2. From things theorems like 2, I know that

$$x^y \pmod{pq} \equiv_{pq} (x^y)^1 \pmod{(p-1)(q-1)} \equiv_{pq} x^y \pmod{(p-1)(q-1)}$$

3. So I can rewrite and solve as

$$3^{240} \equiv_{pq} 3^{240 \pmod{(10-1)(7-1)}} \equiv_{pq} 3^{240 \pmod{60}} \equiv_{pq} 3^0 \equiv_{pq} 1$$

- **[FA15.2.b]** Write about polynomial intersections here. $P(x) - Q(x) = 0$ is max deg 4, so it has 4 roots, answer is 4.
- Note: $n + x \equiv_n x \pmod{n}$.
- Note: Modulo over polynomials should be *prime*.
- General errors. Remember that for $E(x) = \prod_i (x - err_i)$, the err_i is an x value (!!!) and NOT a y value. It is an index.

Counting

- **Stars and Bars**. If k bars and n stars, $\binom{n+k}{k} = \binom{n+k}{n}$ ways. I promise.
- **Bins**. Convert to stars and bars problem with $(\text{numBins} - 1)$ bars.
- Don't forget the general sum rule: $\forall S, T, \quad |S \cup T| = |S| + |T| - |S \cap T|$.

Computability

- **Q [FA15.5.a]** Meaning of “undecidable”? **A:** an undecidable problem is a decision problem for which it is known to be impossible to construct a single algorithm that always leads to a correct yes-or-no answer.
- **[FA15.5.a]** Master: halting problem, programs that return themselves.
- **Quine**: A program that prints itself.

Print out the following sentence twice, the second time in quotes:

‘Print out the following sentence twice, the second time in quotes:’

↪ We can always write quines in any programming language.

↪ Another example:

(Quine “s”) (s “s”)

which, if passed in $s = \text{Quine}$, will output (Quine “s”), which means we run the string s (now interpreted as a program) on itself.

- **Theorem:** *Given any program $P(x, y)$, we can always “convert it” to another program $Q(x)$ such that $Q(x) = P(x, Q)$, i.e. Q behaves exactly as P would if its second input is the description of the program Q .*

→ Halting Problem.

- ⊛ Proof relies on (1) self-reference, and (2) fact that we can't separate programs from data.
- ⊛ Problem: Given the **description P of a program** and its input, write a program **TestHalt** that behaves as:

$$\text{TestHalt}(P, x) = \begin{cases} \text{“yes”} & \text{if } P \text{ halts on input } x \\ \text{“no”} & \text{if } P \text{ loops on input } x \end{cases} \quad (46)$$

- ⊛ Proof: Try feeding program P the input P (itself as bitstring). Define

```
def Turing(P):  
    if TestHalt(P, P) == "yes":  
        loop forever  
    else:  
        halt
```

and consider behavior of $\text{Turing}(\text{Turing})$. It leads to proof by contradiction that $\text{TestHalt}(P, P)$ cannot exist, since that was our main assumption this whole time.

→ **Reduction/TestEasyHalt [HARD]**

- ☞ General pattern to recognize for problem-solving: Try **reducing** (changing) the problem into the general form of the halting problem.

General Tips

- ★ Repeated squaring: It's easier if you write within the equation as you go. Example:

$$x^{16} \pmod{y} = (x^2)^8 \pmod{y} = ((x^2)^2)^4 \pmod{y} = \dots$$

- ★ Write down cardinality of as many sets as possible and whether or not they are countable.
- ★ Rational numbers have decimal expansions that are either finite or periodic.

Bayes' Rule, Independence, Mutual Independence: October 19

Table of Contents Local

Scribe: Brandon McKinzie

*Note: This lecture (23) corresponds to **Note 14** (Combinations of Events).*

Conditional Probability Review.

- A and B positively correlated: $Pr(A|B) > Pr(A)$; Negatively correlated if $Pr(A|B) < Pr(A)$
- $B \subset A \implies$ A and B positively correlated.
- $A \cap B = \emptyset \implies$ A and B negatively correlated.
- Total probability rule: $Pr(B) = Pr(A \cap B) + Pr(\bar{A} \cap B)$.
- **True:** If $Pr(A|B) > Pr(A)$, then $Pr(B|A) > Pr(B)$.
- **False:** If $Pr(C|A) > Pr(C|B)$, then $Pr(A|C) > Pr(B|C)$.
- See lec at [18:00] for square-space probability illustration.

Independence. Two events A and B are independent if any of the (equivalent) statements hold:

$$Pr(A \cap B) = Pr(A)Pr(B) \quad (47)$$

$$Pr(A|B) = Pr(A) \quad (48)$$

$$Pr(B|A) = Pr(B) \quad (49)$$

Examples:

- When rolling two dice, one blue and one red, define events $A =$ sum is 7 and $B =$ red die is 1. **Q:** Are these independent events?²⁷ **A:** Yes.
- Now define events $A =$ sum is 3 and $B =$ red die is 1. **Q:** Are these independent events? **A:** no.

²⁷I'm predicting yes they are, because having the sum be seven doesn't tell us any information about which colored die was what. You were right but for the wrong reason. The sum does actually give us some info in general, but the only reason it doesn't here is because it is 7, which is a possibility regardless of what the first die says. See the next example, which shows a case where they are not independent.

Mutual Independence. Events $\{A_j, j \in J\}$ are mutually independent if

$$Pr(\cap_{k \in K}) = \prod_{k \in K} Pr(A_k) \quad (50)$$

for all finite $K \subseteq J$.

- **Theorem:** *If all K_n are pairwise disjoint finite subsets of J , then events V_n defined by $\{A_j, j \in K_n\}$ are mutually independent.* Proof is in Note 25 example 2.7.
- **Fact:** $(A, B, C, \dots, G, H \text{ mutually indep. }) \implies (A, B^C, C, \dots, G^C, H \text{ mutually indep. })$.
Inductive Proof. Need to show eq 50 holds regardless of which events we take complement of or not. Proceed by induction on n , *the number of complements*. Base case For $n = 0$, this is the normal definition of mutual independence. Hypothesis: Assume true for n . Step. For $n + 1$, need²⁸

$$A \cap B^c \cap C \cap \dots \cap G^c \cap H = X \cap H \setminus X \cap G \cap H \quad (51)$$

where $X := A \cap B^c \cap C \cap \dots \cap F$. Recognize that $X \cap G \cap H \subset X \cap H$.

²⁸Note: The **relative complement** of A with respect to B, denoted as $A \setminus B$, is defined as all objects that belong to A and not to B.

Balls, Coupons, and Random Variables: October 26

Table of Contents Local

Scribe: Brandon McKinzie

*Note: This lecture (25) corresponds to **Note 16** (Random Variables, Distribution, Expectation).*

Balls in bins. Have n bins and $m < n$ balls. Randomly (uniformly) throw balls, one by one, into bins. **Q:** What is the probability that after some m balls, that we don't have any collisions? (no two balls in same bin)²⁹. Result:

$$Pr(\text{no collision}) \approx e^{-\frac{m^2}{2n}} \quad (52)$$

Coupons. Say there are large $n \gg 1$ number of unique possible baseball cards. Each cereal box has a random card. You buy m boxes. The probability that you don't get a particular card (approx), and also a bound on the probability that you miss at least one card is shown below.

$$Pr(\text{miss a specific card}) \approx e^{-\frac{m}{n}} \quad (53)$$

$$Pr(\text{miss at least one card}) \leq ne^{-\frac{m}{n}} \quad (54)$$

²⁹Similar to having m people in room and wanting probability that no two people have same birthday ($n = 365$)

Random Variables. Define random variable X to be the function $X : \Omega \rightarrow \mathbb{R}$ that assigns the value $X(\omega)$ to outcome ω . For more, see portion of section ?? on random variables. The **expected value** of a (discrete) random variable X is

$$\mathbb{E}[X] = \sum_a a \Pr(X = a) \quad (55)$$

$$= \sum_{\omega} X(\omega) \Pr(\omega) \quad (56)$$

where subscript a denotes all possible values of X , and ω denotes all possible outcomes in the sample space.

This suggests that if we repeat an experiment a large number N of times and denote X_1, \dots, X_n as the successive values we get, then

$$\mathbb{E}[X] \approx \frac{\sum_i X_i}{N} \quad (57)$$

Summary. If asked on final the definition of random variable X , write the following:

X is a real-valued function of the outcome of a random experiment.

and some useful properties:

- $\Pr(X = a) := \Pr(X^{-1}(a)) = \Pr(\{\omega | X(\omega) = a\})$ “The probability that X takes on the value a = The probability that random outcome of experiment happens to map into a ”
- $\Pr(X \in A) := \Pr(X^{-1}(A))$.
- The **distribution** of X is the list of possible values and their probability:

$$\{(a, \Pr(X = a)), a \in \mathcal{A}\}$$

where A is the range of X .

Fall 2016

Expectation; Geometric and Poisson: October 28

Table of Contents Local

*Scribe: Brandon McKinzie***Lecture Overview:**

- Review Random Variables.
- Expectation.
- Linearity of Expectation.
- Geometric Distribution.
- Poisson Distribution.

Review of Random Variables. Note that definition of the inverse of a random variable is defined as

$$\forall a \in \mathbb{R} \quad X^{-1}(a) := \{\omega \in \Omega | X(\omega) = a\} \quad (58)$$

and the probability the $X = a$ is defined as $Pr(X = a) = Pr(X^{-1}(a))$. Functions of random variables: Let X, Y, Z be random variables on Ω and $g : \mathbb{R}^3 \rightarrow \mathbb{R}$. Then $g(X, Y, Z)$ is the random variable that assigns the value $g(X(\omega), Y(\omega), Z(\omega))$ to ω .

Expectation. The expectation of a random variable X is

$$\mathbb{E}[X] = \sum_a Pr(X = a)a \quad (59)$$

Example of an **indicator**: Let A be an event. The random variable X defined by

$$X(\omega) = \begin{cases} 1 & \text{if } \omega \in A \\ 0 & \text{if } \omega \notin A \end{cases} \quad (60)$$

is called the **indicator of the event A**. Note that $Pr(X = 1) = Pr(A)$ and $Pr(X = 0) = 1 - Pr(A)$. Hence $\mathbb{E}[X] = Pr(A)$. **Equivalent Notation:** Sometimes also denote indicators like

$$1\{\omega \in A\} \text{ or } 1_A(\omega) \quad (61)$$

Linearity of Expectation. The mean value of a linear combination of random variables is a linear combination of the mean values:

$$\mathbb{E}[a_1X_1 + \cdots + a_nX_n] = a_1\mathbb{E}[X_1] + \cdots + a_n\mathbb{E}[X_n] \quad (62)$$

The common pattern I'm seeing for using linearity is the following: Some generic situation where we might be tempted to let X denote the number of [blank], but the distribution of $Pr(X = [\text{blank}])$ is complicated for taking expectations. Try instead: Let $X = X_1 + \cdots + X_n$, where each X_i represents i th occurrence of [blank] (in which case it is 1) or it is zero if i th occurrence doesn't happen. Useful: Assume A and B are disjoint events. Then

$$1_{A \cup B}(\omega) = 1_A(\omega) + 1_B(\omega) \quad (63)$$

$$1_{A \cup B}(\omega) = 1_A(\omega) + 1_B(\omega) - 1_{A \cap B}(\omega) \quad (64)$$

where the second equation is the more general case where we don't know A and B are disjoint.

- Recall that the expectation of a function of X is given by the following (equivalent) formulas:

$$\mathbb{E}[g(X)] = \sum_x g(x)Pr(X = x) \quad (65)$$

$$= \sum_{\omega} g(X(\omega))Pr(\omega) \quad (66)$$

- **Monotonicity.** Let X, Y be two random variables on Ω . We write $X \leq Y$ if $X(\omega) \leq Y(\omega)$ for all $\omega \in \Omega$. (a) If $X \geq 0$ then $\mathbb{E}[X] \geq 0$; and (b) If $X \leq Y$, then $\mathbb{E}[X] \leq \mathbb{E}[Y]$.

Geometric Distribution. Example: flip a coin *until* we get heads (H), where $Pr(H) = p$. Our sample space is then $\Omega = \{\omega_n, n = 1, 2, \dots\}$ where $\omega_i = T_1, T_2, \dots, T_{i-1}, H$. Let $X(\omega_n) = n$ be the number of flips required to get the first H. This random variable has a **geometric distribution**, defined as

$$Pr(X = n) = p(1 - p)^{n-1} \quad n \geq 1 \quad (67)$$

where $\mathbb{E}[X] = 1/p$. Distribution is *memoryless*:³⁰

Theorem: Let X be $G(p)$. Then, for $n \geq 0$, $Pr(X > n) = (1 - p)^n$, and

$$Pr(X > n + m \mid X > n) = Pr(X > m) \quad m, n \geq 0 \quad (68)$$

Poisson Distribution. Experiment: Flip a coin n times. Told that coin is such that $Pr(H) = \lambda/n$. Let random variable $X = \text{Binom}(n, \lambda/n)$ be number of heads. The **Poisson distribution** of X is the distribution of X for “very large n ”.

We expect $X \ll n$. For $m \ll n$, one has

$$Pr(X = m) = \binom{n}{m} p^m (1 - p)^{n-m} \quad (69)$$

$$\approx \frac{\lambda^m}{m!} \left(1 - \frac{\lambda}{n}\right)^n \quad (70)$$

$$= \frac{\lambda^m}{m!} e^{-\lambda} \quad (71)$$

where $\lambda > 0$ and $m \geq 0$. The mean value is $\mathbb{E}[X] = \lambda$.

If you count the number of times something rare happens, it tends to have a Poisson distribution.

³⁰Carry out 1st trial, and one of two outcomes occurs: success (w/prob p) and we are done (only took 1 trial until success); OR failure (w/prob $1-p$) and we are right back where we started. In the latter case, how many trials do we expect until our 1st success? $1 + \mathbb{E}[X]$: we have already used one trial, and we expect $\mathbb{E}[X]$ more trials since nothing has changed from our original situation. Hence $\mathbb{E}[X] = p \cdot 1 + (1 - p) \cdot (1 + \mathbb{E}[X])$

Review/Summary.

- Formulas for the **expectation** of any discrete random variable X , any function $f(X)$, and any function over many RVs $f(X_1, \dots, X_n)$ are below.

$$\mathbb{E}[X] = \sum_{\omega \in \Omega} X(\omega)P(\omega) = \sum_x xP(X = x) \quad (72)$$

$$\mathbb{E}[f(X)] = \sum_{\omega \in \Omega} f(X(\omega))P(\omega) = \sum_x f(x)P(X = x) \quad (73)$$

$$\mathbb{E}[f(X_1, \dots, X_n)] = \sum_{x_1, \dots, x_n} f(x_1, \dots, x_n)P(X_1 = x_1, \dots, X_n = x_n) \quad (74)$$

- For any *independent* RVs X and Y , $\mathbb{E}[XY] = \mathbb{E}[X]\mathbb{E}[Y]$.
- (**Tail Sum Formula**) Let X be an RV that only takes on values in \mathbb{N} . Then

$$\mathbb{E}[X] = \sum_{x=1}^{\infty} P(X \geq x) \quad (75)$$

- **Discrete Probability Distributions**

→ **Uniform** $\{1, \dots, n\}$. $\mathbb{E}[X] = \frac{n+1}{2}$

→ **Bernoulli**. Special case of binomial distribution where $n = 1$. $Ber(p)$. $\Omega = \{Success, Failure\}$. $P(success) = p$. $\mathbb{E}[X] = p$.

$$X(\omega) = \begin{cases} 0 & \omega = \text{Fail} \\ 1 & \omega = \text{Success} \end{cases} \quad P(X = x) = \begin{cases} 1-p & x = 0 \\ p & x = 1 \\ 0 & \text{otherwise} \end{cases} \quad (76)$$

Indicator RVs³¹. Let $A \subseteq \Omega$ be an event. Define the *indicator of A* as

$$1_A(\omega) = \begin{cases} 0 & \omega \notin A \\ 1 & \omega \in A \end{cases} \quad (77)$$

$\forall k \geq 1 \quad X = X^2 = X^k$.

→ **Binomial**. $Bin(n, p)$. Number of successes in n independent trials where each trial has probability p of success. $\mathbb{E}[X] = \mathbb{E}[X_1 + \dots + X_n] = np$.

→ **Geometric**. $Geom(p)$: the number of independent trials required to obtain the first success, where each trial has prob p of success. $P(X = x) = (1-p)^{x-1}p$, $x \in \mathbb{Z}^+$.

$$P(X > x) = (1-p)^x = 1 - P(X \leq x) \quad \mathbb{E}[X] = 1/p \quad (78)$$

³¹Indicators are basically just Bernoulli RVs.

→ **Negative Binomial.** (Generalization of geometric): How many trials x (each with prob success p) do we need until we obtain k successes?. Key idea: *the last success must occur on the x th trial.*

$$Pr(X = x) = \binom{x-1}{k-1} p^k (1-p)^{x-k} \quad x = k, k+1, \dots \quad (79)$$

$$\mathbb{E}[X] = \sum_{i=1}^k i \mathbb{E}[X_i] = \frac{k}{p} \quad (80)$$

where X_i is number of trials to obtain i th success starting after we've already observed $i-1$ successes.

Coupons and Independent RVs: October 31

Table of Contents Local

Scribe: Brandon McKinzie

[started at 3:16]

Lecture Overview:

- Time to Collect Coupons.
- Review: Independence of Events.
- Independent RVs.
- Mutually Independent RVs.

Coupon Collectors Problem. There are n coupons to collect, each equally likely, and we sample with replacement. What is the probability that more than t sample trials are needed to collect all n coupons?

- Asymptotic. The expected number of trials grows as $\mathcal{O}(n \log n)$.
- Key ideas: It takes very little time to collect the first few coupons, and much longer to collect the the last few. Idea: split the total time into n intervals (for problem of n coupons) where the expected time *can* be calculated.

The RV is X : time to get n coupons. So X_1 is time to get first coupon.

- First few cases: $\mathbb{E}[X_1] = 1$. Probability of getting a new coupon after we've drawn one coupon is just

$$p = \frac{n-1}{n} \tag{81}$$

and so $\mathbb{E}[X_2]$ is geometric. $\mathbb{E}[X_2] = 1/p = n/(n-1)$.

- In general:

$$Pr(\text{get new coupon} | \text{have } i - 1) = \frac{1}{p} = \frac{n - (i - 1)}{n} \quad (82)$$

$$\mathbb{E}[X] = \mathbb{E}[X_1] + \mathbb{E}[X_2] + \cdots + \mathbb{E}[X_n] = n \left(1 + \frac{1}{2} + \cdots + \frac{1}{n} \right) \quad (83)$$

$$=: nH(n) \approx n(\ln n + \gamma) \quad (84)$$

where $H(n)$ is the **Harmonic sum**:

$$H(n) = 1 + \frac{1}{2} + \cdots + \frac{1}{n} \approx \int_1^n \frac{1}{x} dx = \ln n \quad (85)$$

Independence Review (*Events*). Events A , B , C are mutually independent if

$$Pr(A \cap B \cap C) = Pr(A)Pr(B)Pr(C)$$

and all events are pairwise independent.

Independence for *Random Variables*. The RVs X and Y are independent IFF

$$Pr(Y = b | X = a) = Pr(Y = b) \text{ for all } a \text{ and } b \quad (86)$$

which is equivalent to having

$$Pr(X = a, Y = b) = Pr(X = a)Pr(Y = b) \text{ for all } a \text{ and } b \quad (87)$$

- **Theorem:** X and Y are independent if and only if

$$Pr(X \in A, Y \in B) = Pr(X \in A)Pr(Y \in B) \quad \forall A, B \subset \mathbb{R} \quad (88)$$

where the proof of the only if direction uses the following:

$$Pr(X \in A, Y \in B) = \sum_{a \in A} \sum_{b \in B} Pr(X = a, Y = b) \quad (89)$$

- **Theorem:** *Functions of independent RVs are independent.* Restated, this says: Let X, Y be independent RVs. Then $f(X)$ and $g(Y)$ are independent, for all $f(\cdot), g(\cdot)$.

Proof:

1. Recall the definition of **inverse image**:

$$h(z) \in C \iff z \in h^{-1}(C) := \{z | h(z) \in C\} \quad (90)$$

2. We can use this to check that $f(X)$ and $g(Y)$ are independent.

$$Pr(f(X) \in A, g(Y) \in B) = Pr(X \in f^{-1}(A), Y \in g^{-1}(B)) \quad (91)$$

but since we know the RVs X and Y are independent, we can split the probabilities and convert them back to yield desired result.

- **Theorem:** Let X, Y be independent RVs. Then $\mathbb{E}[XY] = \mathbb{E}[X]\mathbb{E}[Y]$

Proof:

1. Important to realize that XY is a *function* of X and Y . Recall that

$$\mathbb{E}[g(X, Y)] = \sum_{x, y} g(x, y) Pr(X = x, Y = y) \quad (92)$$

2. Using this, it is straightforward to complete the proof, a few key parts of which are shown below.

$$\mathbb{E}[XY] = \sum_{x, y} xy Pr(X = x, Y = y) \quad (93)$$

$$= \sum_x \left[x Pr(X = x) \left(\sum_y y Pr(Y = y) \right) \right] \quad (94)$$

Mutually Independent RVs. X, Y, Z are mutually independent if

$$\Pr(X = x, Y = y, Z = z) = \Pr(X = x)\Pr(Y = y)\Pr(Z = z) \quad \forall x, y, z \quad (95)$$

Theorem: *The events A, B, C are pairwise (mutually) independent iff the random variables $1_A, 1_B, 1_C$ are pairwise (mutually) independent.*

→ Note: If X, Y, Z are pairwise independent, but not mutually independent, it may be that $f(X)$ and $g(Y, Z)$ are not independent.

Variance, Inequalities, and WLLN: November 2

Table of Contents Local

Scribe: Brandon McKinzie

[started at 4:08PM]

Lecture Overview:

→ Variance

→ Inequalities

Markov

Chebyshev

Variance. Measures the deviation from the mean value. The variance of X is

$$\sigma^2(X) = \text{var}(X) = \mathbb{E}[(X - \mathbb{E}[X])^2] \quad (96)$$

$$= \mathbb{E}[X^2] - \mathbb{E}[X]^2 \quad (97)$$

Examples.

- **Geometric distribution:**³² We know that $\mathbb{E}[X] = 1/p$. Compute

$$\mathbb{E}[X^2] = p + 4p(1-p) + 9p(1-p)^2 + \dots \quad (98)$$

$$= \frac{2-p}{p^2} \quad (99)$$

and therefore $\text{var}(X) = (1-p)/p^2$. Notice that here $\sigma(X) = \sqrt{1-p}/p \approx \mathbb{E}[X]$ for small p .

- **Fixed points.** Number of fixed points in a random permutation of n items³³. Let $X = X_1 + \dots + X_n$ where X_i is indicator variable for i th [fixed point]. For indicator

³²Recall: $\Pr(X = n) = (1-p)^{n-1}p$ for $n \geq 1$ for geom dist.

³³what?

variables,

$$\mathbb{E}[X^2] = \sum_i \mathbb{E}[X_i^2] + \sum_{i \neq j} \mathbb{E}[X_i X_j] \quad (100)$$

$$= n \times \frac{1}{n} + \sum_{i \neq j} \frac{1 \times 1 \times (n-2)!}{n!} \quad (101)$$

$$= n \times \frac{1}{n} + \sum_{i \neq j} \frac{1}{n(n-1)} \quad (102)$$

$$= n \times \frac{1}{n} + n(n-1) \times \frac{1 \times 1 \times (n-2)!}{n!} \quad (103)$$

$$= 1 + 1 = 2 \quad (104)$$

- **Binomial.** Direct calculation is too hard:

$$\mathbb{E}[X^2] = \sum_{i=0}^n i^2 \binom{n}{i} p^i (1-p)^{n-i} \quad (105)$$

Start over with example: Flip coin with head probability p . Let X denote the number of heads after n flips. Use indicators

$$X_i = \begin{cases} 1 & \text{ith flip heads} \\ 0 & \text{otherwise} \end{cases} \quad (106)$$

Now, we can easily find $\mathbb{E}[X_i^2] = 1^2 \times p = p$. Then $\text{Var}(X_i) = p - p^2 = p(1-p)$. It follows that

$$\text{Var}(X) = \text{Var}(X_1 + \cdots + X_n) = np(1-p) \quad (107)$$

Properties of Variance.

$$\text{Var}(cX) = c^2 \text{Var}(X) \quad (108)$$

$$\text{Var}(X + c) = \text{Var}(X) \quad (109)$$

Variance of sums of independent RVs. If X and Y are independent, then

$$\text{Var}(X + Y) = \text{Var}(X) + \text{Var}(Y) \quad (110)$$

To **prove** this, note that shifting the RVs does not change their means, so we can subtract their means. Then $\mathbb{E}[XY] = \mathbb{E}[X]\mathbb{E}[Y] = 0$ which is the cross term we would encounter when calculating $\text{Var}(X + Y)$. Result should follow.

If X, Y, Z, \dots are **pairwise independent**, then

$$\text{Var}(X + Y + Z + \dots) = \text{Var}(X) + \text{Var}(Y) + \text{Var}(Z) + \dots \quad (111)$$

which also uses the fact that we can center all variables to mean 0 to prove.

Inequalities.

- **Markov.** $\Pr(X > a)$. Gives an upper bound. Assume $f : \mathbb{R} \rightarrow [0, \infty)$ is nondecreasing. Then

$$\Pr(X \geq a) \leq \frac{\mathbb{E}[f(X)]}{f(a)} \quad (112)$$

for all a such that $f(a) > 0$. This can be proved using

$$1_{\{X \geq a\}} \leq \frac{f(X)}{f(a)} \quad (113)$$

(some examples at [44:00])

- **Chebyshev.** $\Pr(|X - \mu| > \epsilon)$ Probability the X differs from mean more than ϵ .

$$\Pr(|X - \mathbb{E}[X]| > a) \leq \frac{\text{var}(X)}{a^2} \quad \forall a > 0 \quad (114)$$

Discrete Math and Probability

Confidence Intervals: November 4

Table of Contents Local

Scribe: Brandon McKinzie

Definition: An interval $[a, b]$ is a 95% confidence interval for an unknown quantity θ if

$$Pr(\theta \in [a, b]) \geq 95\% \quad (115)$$

where the interval $[a, b]$ is calculated on the basis of observations. Chebyshev is useful.

Example: Assume that X_1, \dots, X_n are i.i.d and have a distribution that depends on some parameter θ , e.g. $X_n = B(\theta)$.

Coin Flips. Say you flip a coin $n = 100$ times and observe 20 *H*s. If $p := Pr(H) = 0.5$, this event is very unlikely. It is unlikely that the true value of p differs a lot from the observed fraction of heads, A_n . Hence, one should be able to build a confidence interval $[A_n - \delta, A_n + \delta]$ for p . Key idea:

$$|A_n - p| \leq \delta \iff p \in [A_n - \delta, A_n + \delta] \quad (116)$$

$$Pr(|A_n - p| > \delta) \leq 5\% \iff Pr(p \in [A_n - \delta, A_n + \delta]) \geq 95\% \quad (117)$$

For n coin flips, Chebyshev will show us that $\delta = 2.25/\sqrt{n}$ gives the 95% CI.

Theorem: Let X_n be i.i.d. with mean μ and variance σ^2 . Define $A_n = \frac{X_1 + \dots + X_n}{n}$. Then

$$Pr\left(\mu \in \left[A_n - 4.5\frac{\sigma}{\sqrt{n}}, A_n + 4.5\frac{\sigma}{\sqrt{n}}\right]\right) \geq 95\% \quad (118)$$

Example: Let $X_n = 1\{\text{coin } n \text{ yields H}\}$. Then

$$\mu = \mathbb{E}[X_n] = p := Pr(H) \quad (119)$$

$$\sigma^2 = \text{var}(X_n) = p(1-p) \leq \frac{1}{4} \quad (120)$$

“Hence, $\left[A_n - 4.5\frac{1/2}{\sqrt{n}}, A_n + 4.5\frac{1/2}{\sqrt{n}}\right]$ is a 95% CI for p .” Note that this CI is actually guaranteed to be *at least* 95% confidence.

CI Analysis: Time to prove the theorem above. Chebyshev inequality states that

$$Pr \left[|A_n - \mu| \geq 4.5\sigma/\sqrt{n} \right] \leq \frac{\text{var} A_n}{(4.5\sigma/\sqrt{n})^2} \quad (121)$$

where all X_i used to calculate the fraction A_n satisfy $\mathbb{E}[X_i] = \mu$. Thus $\mathbb{E}[A_n] = n\mu/n = \mu$ as well. We use properties of the variance to compute

$$\text{var}(A_n) = \frac{1}{n^2} \text{var}(X_1 + \cdots + X_n) \quad (122)$$

$$= \frac{1}{n^2} (\text{var}(X_1) + \cdots + \text{var}(X_n)) \quad (123)$$

$$= \frac{1}{n^2} \cdot n\sigma^2 = \frac{\sigma^2}{n} \quad (124)$$

and therefore A_n , our estimate for the probability of H, has a variance that shrinks like $1/n$. Now we can continue our calculation

$$Pr \left[|A_n - \mu| \geq 4.5\sigma/\sqrt{n} \right] \leq \frac{n}{20\sigma^2} \times \frac{1}{n}\sigma^2 = 5\% \quad (125)$$

Geometric CI. Want CI for $1/p$ in $G(p)$ ³⁴. **Theorem:** Let X_n be i.i.d. $G(p)$. As usual define $A_n = (X_1 + \cdots + X_n)/n$. Then

$$\left[\frac{A_n}{1 + 4.5/\sqrt{n}}, \frac{A_n}{1 - 4.5/\sqrt{n}} \right] \text{ is a 95\% CI for } \frac{1}{p} \quad (126)$$

³⁴Recall that $\mathbb{E}[X] = 1/p$, the expected number of trials until first success, where each (independent) trial has probability of success p .

Which coin is Better? Given two coins A and B . **Goal:** Figure out which coin has larger $Pr(H)$. Let p_A and p_B be the $Pr(H)$ for each of the two coins. **Approach:**

- Flip each coin n times.
- Assume we observe $A_n > B_n$.
- What is our confidence that $p_A > p_B$?

Analysis:

$$\mathbb{E}[A_n - B_n] = p_A - p_B \quad (127)$$

$$var(A_n - B_n) = \frac{1}{n} (p_A(1 - p_A) + p_B(1 - p_B)) \quad (128)$$

$$\leq \frac{1}{2n} \quad (129)$$

$$Pr[|A_n - B_n - (p_A - p_B)| > \delta] \leq \frac{1}{2n\delta^2} \quad (130)$$

$$Pr[p_A - p_B \in [A_n - B_n - \delta, A_n - B_n + \delta]] \geq 1 - \frac{1}{2n\delta^2} \quad (131)$$

$$Pr[p_A - p_B \geq 0] \geq 1 - \frac{1}{2n(A_n - B_n)^2} \quad (132)$$

Unknown σ . Sometimes it may be OK to replace σ^2 by the following **sample variance**:

$$s_n^2 := \frac{1}{n} \sum_{m=1}^n (X_m - A_n)^2 \quad (133)$$

“The theory says it is OK if the distribution of X_n is nice (Gaussian).”
